### 1. ABSTRACT

The tropical liver fluke, *Fasciola gigantica* is a food-borne parasite responsible for the hepatobiliary disease fascioliasis. The recent completion of *F. gigantica* genome sequencing by our group has provided a platform for the systematic analysis of the parasite genome. Eukaryotic protein

kinases (ePKs) are regulators of cellular phosphorylation. In the present study, we used various computational and bioinformatics tools to extensively analyse the ePKs in *F. gigantica* (FgePKs) genome. A total of 455 ePKs were identified that represent ~2% of the parasite genome.

### **F. gigantica eukaryotic protein kinases**

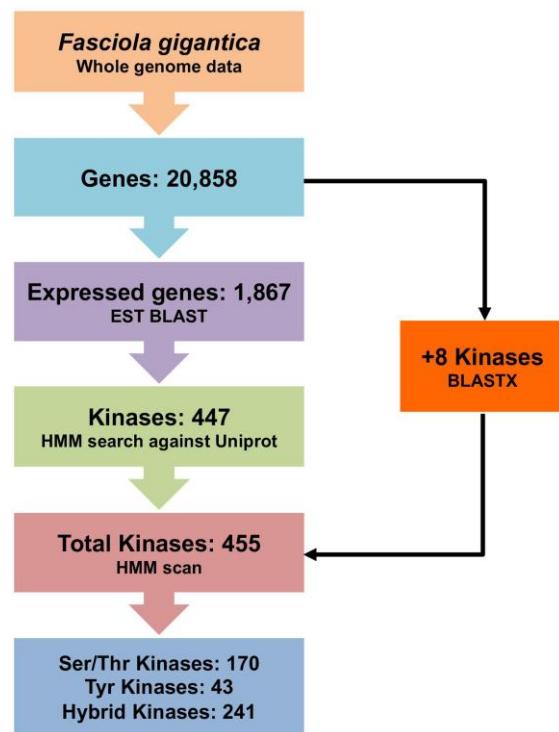

Out of these, 214 ePKs are typical kinases (Ser/Thr- and Tyr-specific ePKs), and 241 were other kinases. Several FgePKs were found to possess unusual domain architectures, which suggests the diverse nature of the proteins that can be exploited for designing novel inhibitors. 115 kinases showed <35% query coverage when compared to human ePKs highlighting significant divergences in their respective kinomes, further providing a platform for novel structure-based drug designing. This study provides a platform that may open new avenues into our understanding of helminth biochemistry and drug discovery.

## **2. INTRODUCTION**

Fascioliasis is primarily an infection of the livestock caused by *F. hepatica* and *F. gigantica*. It is a severe food-borne neglected tropical disease (NTD) that causes massive health and economic loss in the developing countries of the tropics and subtropical areas (1-4). *Fasciola* spp. has a worldwide distribution and it infects livestock, such as cattle, sheep, and goats resulting in an estimated economic loss of more than 3 billion USD per annum worldwide (4-6). Humans become accidental hosts through consumption of watercress or other fresh aquatic vegetation or by drinking water contaminated with viable parasite metacercariae. Once the larvae are ingested, they develop into adult flukes inside the host and start feeding on the liver tissues. As a result, the liver becomes dysfunctional, and the pathology is characterized by severe damage to the liver tissues and bile ducts (7). According to the World Health Organization (WHO) estimates, at least 2.4 million people are infected worldwide, and 180 million are at risk of infections (8, 9). Fascioliasis is principally treated with a single WHO-approved drug triclabendazole (TCBZ), but recent studies report increasing cases of TCBZ-resistant flukes in Europe, Australia, and in more than 70 countries across the world (10-14). Therefore, the development of new therapeutics against these platyhelminthic parasites is one of the most important challenges for researchers.

Signal transduction through the integration of protein phosphorylation and

dephosphorylation by specialized enzymes are essential to respond to certain extracellular signals that help maintain homeostasis as well as other complex cellular adaptation in parasites. Various protein functions, such as cell division, cellular metabolism, growth, differentiation, survival, and apoptosis are regulated through phosphorylation by protein kinases (PKs) that cause alterations in the protein structure by covalent modifications, and hence, facilitates the formation of hydrogen bonds among specific amino acid residues for mediating intracellular signals (15). Protein kinases catalyse the transfer of  $\gamma$ -phosphate from high energy molecules like ATP or GTP to its polypeptide substrates, thereby, modulating their structures and functions. The action of PKs is reversed by phosphatases that remove phosphoryl moieties from their substrates. Structurally, most PKs contain a catalytic domain responsible for binding and phosphorylating target proteins, and a regulatory domain for maintaining a catalytically inactive state to prevent constitutive substrate phosphorylation (16). Protein kinases are either auto phosphorylated or get phosphorylated by other PKs (17). The catalytic core of the PKs consists of a Gly-rich ATP/GTP binding domain in the N-terminus and a conserved Asp residue in the centre (18). Substrate recognition by PKs employs two types of interactions: (i) recognition of the consensus phosphorylation sequence by the active site residues and (ii) distal interactions between the PK and the substrate mediated by regions away from the phosphorylation site in the substrate and regions in PK located distally from its active site. Protein kinases are classified into two superfamilies: (i) the eukaryotic or conventional protein kinases (ePKs), and (ii) the atypical protein kinases (aPKs). The sequences of the aPKs are different than those of ePKs but show kinase activity (18). Based on the phosphate acceptor site in the substrate, ePKs are classified into Ser/Thr kinases (STKs) and Tyr kinases (TKs). Kinases that specifically phosphorylate both Ser/Thr and Tyr are also found (19). The ePKs are grouped according to their homologous catalytic domains, which generally consist of 250-300 amino acid residues (20, 21). According to KinBase (19), ePKs have been classified into eight groups: AGC (cAMP-dependent Protein Kinase or

**Figure 1.** Schematic representation of the methods used for prediction and classification of the *F. gigantica* ePKs.

Protein Kinase A/Protein Kinase G/Protein Kinase C), CAMK (Calcium/Calmodulin regulated Kinases), CK1 (Cell Kinase I), CMGC (Cyclin-dependent Kinases and other close relatives), RGC (Receptor Guanylate Cyclases), STE (Sterile Ser/Thr Kinases), TK (Tyr Kinase), and TKL (Tyr Kinase-Like). In addition, a ninth group called "Other kinases" exists, consisting of several kinases that cannot be classified into any of the above families (22). Many PK inhibitors have been developed and approved for the treatment of different human diseases, including infections with parasitic helminth, like *Schistosoma mansoni* (the blood fluke) (23, 24).

Recent sequencing of the *F. gigantica* genome (25) has provided a crucial platform for further exploration of the biochemistry of the parasite. Understanding the structure and function of proteins encoded by the genome of this platyhelminthic parasite will provide information for structure-based drug design and development. Therefore, the study of the ePKs of

*F. gigantica* is a major step towards these goals. Alteration in the functionality of these enzymes may result in a cascade of pathological signs that might contribute to the mortality of the parasite. Thus, the present work aims at analysing the *F. gigantica* genome by combined computational approaches, including Hidden Markov Models (HMMs) and phylogenetic analyses to identify all the ePKs encoded in the genome; and to identify potential kinases having a special role in the signalling process of the parasite to utilize them as a novel drug target against *F. gigantica*. The schematic representation of the methodology is shown in Figure 1.

### 3. METHODS

#### 3.1. *F. gigantica* gene sequence retrieval

The whole genome data of *F. gigantica* (accession number: MKHB00000000) showed a total of 20,858 genes (25). Gene sequences were then submitted to BLAST against expressed search tag (EST) to ascertain the expressed genes.

#### 3.2. Generation of hidden markov models (HMMs)

Potential ePKs of *F. gigantica* (FgePKs) were identified and characterized by combined approaches based on sequence similarity and phylogenetic relationships. The gene sequences were further translated to amino acid sequences using SMS server (<http://www.bioinformatics.org/sms2/translate.html>) to run HMMs. Alignments were generated in Mega v7 ([www.megasoftware.net](http://www.megasoftware.net)) using the clustalW algorithm with default parameters. The HMM search was performed against the Uniprot database for identifying ePK-like proteins of *F. gigantica* based on similarity. Also, the 20,858 *F. gigantica* genes were directly submitted to BLASTX that annotates the genes based on sequence similarity by converting the gene sequences into protein sequences. The potential FgePKs, obtained from both HMMsearch and BLASTX results, were compared and used for further analysis.

### 3.3. Classification and domain analysis of FgePKs

The obtained FgePKs were functionally classified into groups, families, and subfamilies and their conserved domains were identified. The classified ePKs were further evaluated in Kinbase. Domain analysis was performed by HMMscan for identifying the conserved catalytic domain of the FgePKs based on the data available at the Protein families database (Pfam) (26). Further phylogenetic analyses of the FgePKs groups were also performed. The sequences were first aligned and then used for the construction of phylogenetic tree using Mega7 server ([www.megasoftware.net](http://www.megasoftware.net)). Initially, 1000 random datasets (in replicates) were created for each alignment using Seqboot with default parameters. The multiple sequence alignment was used in the Mega7 server to construct the phylogenetic tree using the maximum likelihood method, based on the model of Tamura and Nei (27); all the parameters were kept default.

## 4. RESULTS

### 4.1. Identification of kinase-like proteins in *F. gigantica* genome

A total of 20,858 genes are annotated in the *F. gigantica* genome data (25). A total of 1,867 expressed gene sequences were found when the above gene sequences were submitted to BLAST against EST. The FgePK proteome (*F. gigantica* ePKinome) was predicted using HMMs. This analysis revealed a total of 455 ePKs in the *F. gigantica* proteome, of which 447 were identified in the HMMsearch, while BLASTX revealed the other 8 kinases representing ~2% of the total proteins encoded in the parasite genome (Table 1).

### 4.2. Classification and domain analysis of FgePKs

The FgePKs were identified by analyzing the parasite genome. The total number of ePKs varied in different organisms (*Saccharomyces cerevisiae*, *Drosophila melanogaster*, *Caenorhabditis elegans*, *Plasmodium falciparum*,

*Trypanosoma brucei*, *Trypanosoma cruzi*, *Leishmania major*, *Brugia malayi*, *Schistosoma mansoni*, *Mus musculus*, and *Homo sapiens*) and ranged from 82 to 503 (Figure 2). We observed that *F. gigantica* contains almost twice the number of ePKs compared to the related parasites.

Our data show that *F. gigantica* has representatives in all ePKs groups. Phylogenetic analysis suggests that most of them are distinctly clustered with known ePKs in other eukaryotes. Those ePKs that do not fall into these groups were categorized as "Other". In *F. gigantica* the largest ePKs group was Ser/Thr kinase (170 members), a common feature shared with many organisms, and the smallest group was TKL (only 1 member). The largest and the smallest ePKs group within the Ser/Thr group of FgePKs was AGC (104 members), and STE (only 1 member), respectively. Similarly, in the Tyr kinase group, we found 43 sequences. A total of 241 sequences were designated as other kinases (Figure 3).

#### 4.2.1. Ser/Thr kinase group

The Ser/Thr kinases are generally classified into 5 groups: AGC, CaMK, CMGC, STE, and CK1. In FgePKs, we found proteins belonging to all these groups (Table 2). The AGC group is comprised of protein kinase A (PKA), protein kinase G (PKG), and protein kinase C (PKC). The CaMK represents Calcium and Calmodulin regulated kinases, whereas the CMGC group is comprised of CDK (Cyclin Dependent Kinase), MAPK (Mitogen Activated Protein Kinase), GSK (Glycogen Synthase 3 Kinase), CLK (CDC-Like Kinase), SRPK (SR-rich Protein Kinase), CK2 (Cell/Casein Kinase 2), DYRK (Dual-specificity Tyr Regulated Kinase), and RCK (named after resistance to complement killing, *rck* gene of mouse). The STE and CK1 represent sterile kinase and Casein Kinase 1, respectively.

##### 4.2.1.1. cAMP-dependent protein kinase (AGC) group

The AGC kinases are known to phosphorylate the substrates at Ser/Thr residues present near the basic amino acid residues (Arg and Lys). In eukaryotic organisms, AGC group is comprised of three types of cytoplasmic Ser/Thr

**F. gigantica eukaryotic protein kinases**

**Table 1.** The table shows the 455 FgePKs identified in the *F. gigantica* genome from both EST blast and BlastX results

**Figure 2.** ePKs in the predicted proteomes of diverse taxa. A total of 252 PKs were identified in the predicted proteome of *F. gigantica*. For comparison, the number of the total predicted proteome that codes for ePKs is shown for Sc – *S. cerevisiae*, Dm – *D. melanogaster*, Ce – *C. elegans*, Pf – *P. falciparum*, Tb – *T. brucei*, Tc – *T. cruzi*, Lm – *L. major*, Bm – *B. malayi*, S. mansoni, Mm – *M. musculus*, and Hs – *H. sapiens*.

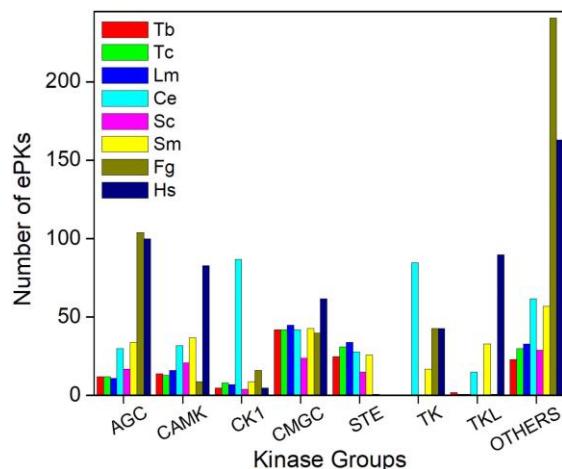

kinases PKA,PKG, and PKC, which are further divided into 16 families, specifically distributed into different forms of life. In the *F. gigantica* ePKs, we

found 101 AGC kinases, of which 99 belonged to PKC, and 2 belonged to PKA; 3 members were G-protein-coupled receptor kinases (GRK), a member of PKC.

### 4.2.1.1.1. Protein kinase C (PKC)

Protein kinase C is regarded as a fundamental regulator of the developmental processes in vertebrates for its pivotal role in cell growth and differentiation (15, 28). Role of PKC is also implicated in lipid signalling. The greater number of PKCs in the FgePKs suggests that this family is crucial for *F. gigantica*, and may be suitable targets for drug development. The PKC belongs to a large protein family that is classified into four subfamilies: PKC alpha ( $\alpha$ ), eta ( $\eta$ ), iota ( $\iota$ ), and delta ( $\delta$ ). In the *F. gigantica* ePKs, we found 6 alpha, 46 eta, 23 iota, and 24 delta PKCs. The PKC alpha family consists of gamma ( $\gamma$ ), beta I ( $\beta$ I), beta II ( $\beta$ II), and alpha subfamilies and are regulated by  $\text{Ca}^{2+}$  and diacylglycerol (DAG). Further, the PKC eta and delta subfamilies encompass the novel PKCs {epsilon ( $\epsilon$ ), delta, eta, and theta ( $\theta$ )}, which are sensitive to DAG;

## F. gigantica eukaryotic protein kinases

**Figure 3.** Distribution of ePKs groups in *F. gigantica* and other organisms. For comparison, occurrence of the different ePKs groups in Tb – *T. brucei*, Tc – *T. cruzi*, Lm – *L. major*, Ce - *C. elegans*, Sc - *S. cerevisiae*, Sm - *S. mansoni*, and Hs - *H. sapiens* are shown.

and PKC iota subfamily contain the atypical PKCs ( $\zeta$  (zeta) and  $\iota$ ), which are insensitive to both  $\text{Ca}^{2+}$  and DAG (15, 29).

*F. gigantica* contains representatives from three out of four PKC alpha subfamilies mentioned above. The six PKC alpha proteins found in *F. gigantica* were  $\gamma$ : XP\_009162854, XP\_009166221, XP\_012802529,  $\beta$ I: XP\_009164837, XP\_9164836, XP\_009174694, and  $\beta$ II: XP\_009166221. XP\_009166221 contains a unique domain C2 (Ca domain; 6-116 residues), which is involved in targeting proteins to cell membranes (Figure 4). A typical PKC-C2 domain has a  $\beta$ -sandwich composed of 8  $\beta$ -strands that coordinate the  $\text{Ca}^{2+}$  ions that bind in a cavity shaped by two loops of the domain (29).

In PKC eta group, protein GAA54209 contains a CNH domain (30), which is found in NIK1-Like kinase, mouse citron, and yeast ROM1, ROM2. In PKC iota group, protein XP\_012796123 had a unique domain called doublecortin (31), which is a microtubule-associated protein expressed by neuronal precursor cells and immature neurons in the embryonic and adult brain cortex. Also, XP\_012795504 showed a unique domain PDZ, which is found in several signalling proteins in all domains of life ranging from bacteria to animals (32).

It plays a key role in anchoring membrane receptor proteins to cytoskeletal components and helps the formation of signal transduction complexes. In PKC delta group, the protein GAA48273 had a unique domain called I-set domain. This domain is present in several cell adhesion molecules and in Tyr protein kinase receptors (33, 34).

The GRKs modulates G-protein-coupled receptors (GPCRs), including the rhodopsin light-sensitive GPCR, and a variety of neurotransmitter receptors. We found 3 GRK proteins in FgePKs: XP\_009162757, GAA48257, and GAA48257.

### 4.2.1.1.2. Protein kinase A (PKA)

The PKA activity is dependent on the cellular levels of cyclic AMP (cAMP), hence also known as the cAMP-dependent protein kinase. cAMP binds to the regulatory subunit of PKA, and then, activate the catalytic subunit. They have several functions, including regulation of glycogen, sugar, and lipid metabolism. The regulatory and catalytic activities are performed by separate gene products known as PKA-R and PKA-C. PKA exists as an inactive heterotetramer with two PKA-R and PKA-C subunits (35). In the FgePKs, two PKA proteins (GAA31871, GAA31871) were found.

### 4.2.1.2. Calmodulin kinase (CaMK) group

Like AGC kinases, the members of CaM kinase also phosphorylate near basic amino acid residues at specific positions in their substrates.  $\text{Ca}^{2+}$  acts as a second messenger in many cellular signaling processes, which in turn, is controlled by CaM-binding kinases. Some members of the CaMK group, such as CaMK1, CaMK2, CaMK4, and MLCK are activated by binding of  $\text{Ca}^{2+}$ /CaM at a domain located in the C-terminus of their catalytic domains (36). In the FgePKs, 9 proteins were classified as CaMK (CDQ66143, XP\_009163606, CCD77707, GAA40887, XP\_009163606, GAA48272, GAA40887, AAX26206, and XP\_009163606).

### 4.2.1.3. Cyclin-dependent kinase and other close relatives (CMGC) group

As in *S. mansoni*, the CMGC kinases are relatively abundant in *F. gigantica*, signifying its requirement in the regulation of cell proliferation, replication, and segregation of organelles, which are

**F. gigantica eukaryotic protein kinases**

## F. gigantica eukaryotic protein kinases

**Figure 4.** Phylogenetic analysis of the *F. gigantica* Ser/Thr kinases. The *F. gigantica* AGC group is shown in blue, the CK1 group is shown in light blue clade and the single STE group member found is shown in green clade, the CaMK group is shown in pink clade and the CMGC group is shown in red clade. Color code: AGC (Blue), CK1 (Cyan), GSK3 (Green), CaMK (pink), and CMGC (Red).

indispensable metabolic processes for parasites with a complex life cycle. In the FgePKs, members belonging to the cyclin-dependent kinase (CDK), such as mitogen-activated protein kinase (MAPK), glycogen synthetase kinase 3 (GSK3), and dual-specificity Tyr regulated kinase (DYRK) were found.

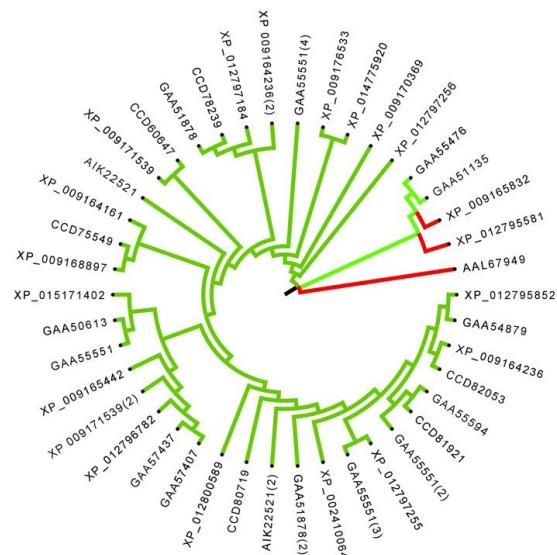

### 4.2.1.3.1. Cyclin dependent kinases (CDK)

In eukaryotes, CDKs interact with cyclin to regulate cell cycle progression (37-39). Twenty-three CDKs were present in FgePKs. The protein XP\_009168739 contains a unique cyclin-dependent kinase regulatory subunit (CKS; 127-182 residues)

domain (40). The CKS is a small hexameric protein (79-150 residues) that can bind six CDKs and is essential for the functioning of CDKs. In yeast (gene cks1) and in fission yeast (gene suc1), a single isoform is known, while mammals have two highly related isoforms (39).

The protein XP\_009171362 contains a unique domain of cdk5 (cell division protein kinase 5) activator (23-155 residues) (41). It is involved in the phosphorylation of the neurofilament proteins, and the Alzheimer's tau protein, and thought to be catalyzed by a protein kinase with Cdc2-Like substrate specificity.

## F. gigantica eukaryotic protein kinases

**Figure 5.** Phylogenetic analysis of the *F. gigantica* Tyr kinases. Color code: RTK (Green), Non-RTK (Pink).

### 4.2.1.3.2. Mitogen activated protein kinases (MAPK)

The MAPK are the closest relatives of CDKs and are involved in the regulation of cell proliferation, gene expression, differentiation, motility, stress response, mitosis, cell survival, and apoptosis (42). They are activated in response to the extracellular stimuli, including mitogens, osmotic stress, heat shock, and pro-inflammatory cytokines. In *F. gigantica*, a total of 15 sequences were found that coded for PKs belonging to MAPK.

### 4.2.1.3.3. Glycogen synthase 3 kinases (GSK3)

The GSK3 is a member of Ser/Thr kinase that mediates the addition of phosphate group to over 40 different proteins involved in a variety of different cellular pathways, including cellular proliferation, migration, glucose regulation, and apoptosis (43). In mammals, GSK3 is encoded by the genes GSK3 alpha (GSK3A) and GSK-3 beta (GSK3B). The role of GSK3 has recently been implicated in a number of diseases, including Alzheimer's disease, type II diabetes, inflammation, cancer, and bipolar disorder. One GSK3 kinase XP\_009172337 was present in the FgePKs.

### 4.2.1.3.4. Dual-specificity Tyr regulated kinases (DYRK)

The DYRKs belong to Ser/Thr kinase groups and also phosphorylate the Tyr residues in the substrates. One DYRK kinase XP\_014775920 was present in the FgePKs.

### 4.2.1.4. Sterile Ser/Thr kinase (STE) group

The STE group consists of homologs of three yeast sterile kinases: STE11, STE7, and STE20. They sequentially activate each other, and then, activate the MAPK family (44). The members of STE11 (MAP3K) phosphorylate STE7 kinases, STE20 members (MAP4K) act on STE11 kinases, and STE7 (MAP2K) members directly phosphorylate MAPKs. The STE20 is the largest of these three and is classified into p21-activated kinase (PAK) and germinal center kinase (GCK) families. One STE20 kinase, GAA30009 was present in the FgePKs.

### 4.2.1.5. Casein kinase 1 (CK1) group

The members of this group prefer Ser/Thr residues present in the C-terminus of a phosphoserine/phospho threonine, although it may often be substituted by a stretch of acidic residues (45). They are involved in Wnt signaling, circadian rhythms, nuclear-cytoplasmic shuttling of transcription factors, DNA repair, and DNA transcription. The CK1 group consists of three main ePK families: CK1, vaccinia related kinase VRK (VRK), and tau tubulin kinase TTBK (TTBK). The FgePKs contained 9 CK1, one VRK kinase, and 6 TTBK kinases.

### 4.2.2. Tyr kinase group

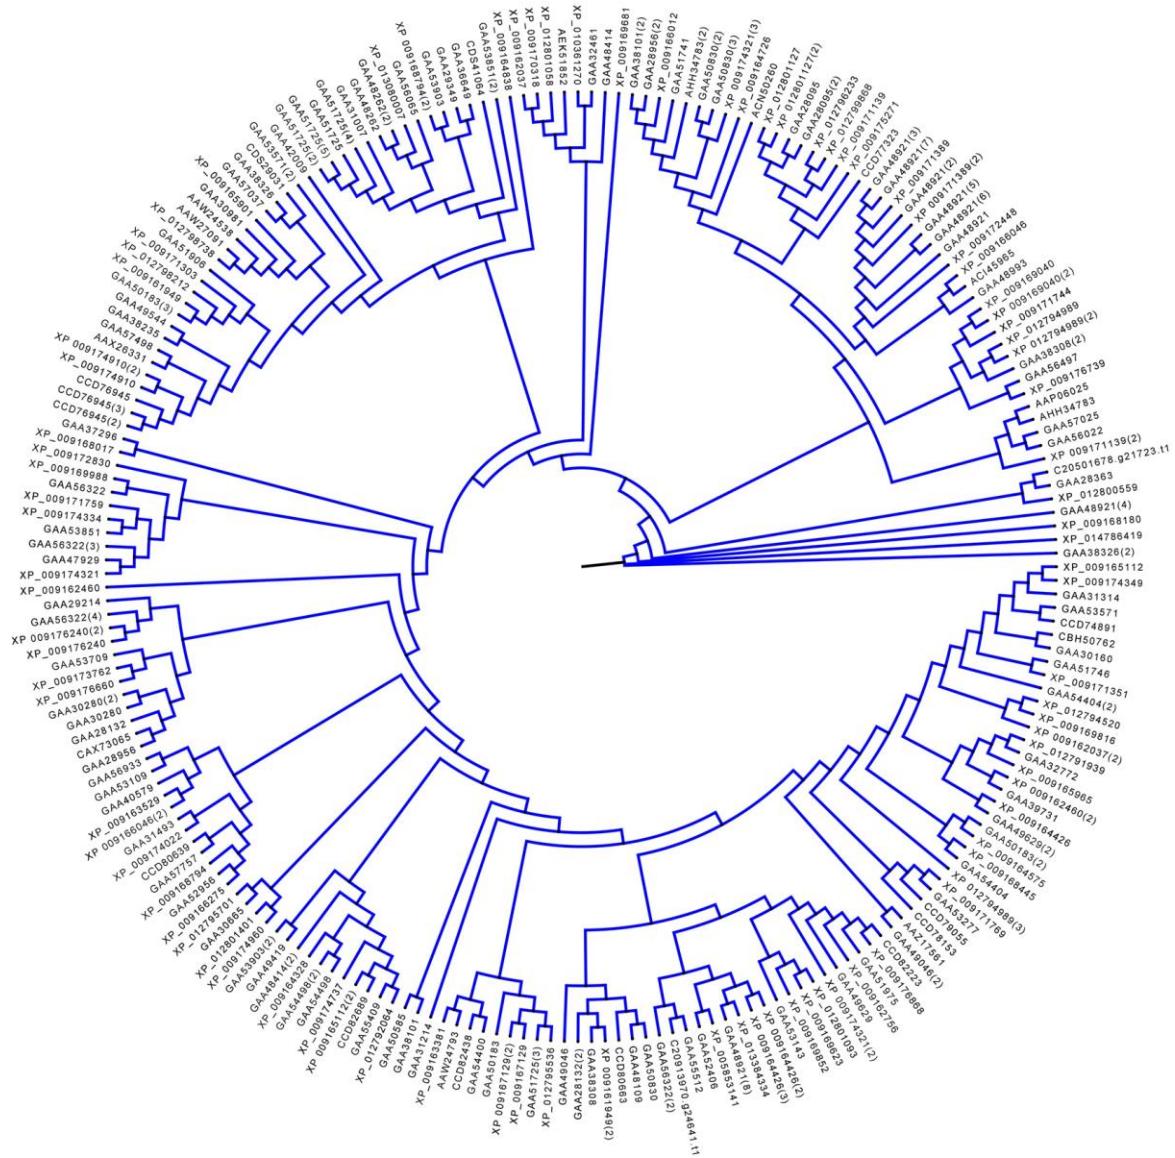

The protein Tyr kinase group has catalytic domains that specifically phosphorylate the Tyr residues in their substrates (46). The TKs can be classified, based on the presence or absence of transmembrane domains, into receptor Tyr kinase and non-receptor Tyr kinase (47). The RTKs have a ligand-binding extracellular domain and an intracellular catalytic domain. The non-RTKs are mainly found in the cytosol, nucleus and in the inner side of the plasma membrane; they are devoid of the transmembrane domain. The FgePKs contained 43 sequences that had Tyr kinase domain (Table 3), of which, 4 were receptor Tyr kinases and 39 were non-receptor Tyr kinases (Figure 5).

## F. gigantica eukaryotic protein kinases

**Figure 6.** Phylogenetic analysis of the *F. gigantica* hybrid kinases. The *F. gigantica* ePKs that were classified into 'others' group are shown here in blue clade.

The protein XP\_009171539 (scaffold85530.g8549.t1) showed three unique domains: 2 PHD (plant homeodomain) (48, 49) and 1 Williams-Beuren syndrome DDT (WSD), D-TOX E motif) domain (49, 50). The PHD finger was discovered in 1993 as a Cys4-His-Cys3 motif in the plant homeodomain (hence, PHD) protein HAT3.1 in *A. thaliana* and maize ZmHox1a. The WSD domain family represents the combined  $\alpha$ -helical

module found in diverse eukaryotic chromatin proteins. The protein XP\_009171539 (scaffold170161.g16225.t1) also showed the presence of the WSD domain. GAA51878 showed three unique domains called SRC Homology Domain (SH3) (51). The SH3 is a small domain consisting of about 60 amino acid residues. This domain is present in phospholipase and several cytoplasmic Tyr kinases, such as Abl and Src (51,

52). It is also present in many other protein families, such as PI3 kinase, Ras GTPase-activating protein, CDC24 and CDC25 (52-54).

GAA50613 and XP\_01279558 showed the presence of unique domains. GAA50613 contains the F-actin binding domain that forms a compact bundle of four antiparallel  $\alpha$ -helices, which are arranged in a left-handed topology. Binding of F-actin to the F-actin binding domain may result in cytoplasmic retention and subcellular distribution of the protein, as well as possible inhibition of protein function (55). XP\_01279558 contains one I-set domain, which is described above in section 4.2.1.1.1 (34).

### 4.3.3. Hybrid group

Hybrid group is divided into two types: TKL (Tyr Kinase-Like) and 'others'. We found total

241 members in this group (Figure 6) (Table 4). The hybrid kinases containing various unique domains are discussed below.

#### 4.3.3.1. Tyr kinase-like (TKL) group

The TKL group is composed of 8 families, including the LISK family that consists of two main subfamilies: LIMK (LIM domain kinases), and TESK (Testis Expressed Serine Kinases) (56). Both TESK and LIMK subfamilies phosphorylate cofilin and inhibit its actin-capping function. In the FgePKs, we found one member from the LIMK (GAA57757) subfamily.

#### 4.3.3.2. Others

The kinases that were not classified in the previous groups are discussed here. A total of 240 FgePKs were found that belongs to this group (Figure 6).

## *F. gigantica* eukaryotic protein kinases

The function of adenylate kinase has been ascribed to *de novo* adenine nucleotide synthesis and cell energy economy through the regulation of nucleotide ratios in different intracellular compartments and AMP-sensitive metabolic enzymes (57). Fourteen adenylate kinases were found in the FgePKs.

In addition to the two adenylate kinases, few more proteins from the 'others' kinase group possessed unique domains. XP\_009169988 contains the HR1 domain. The HR1 repeat was first defined in the N-terminal non-catalytic part of protein kinase PRK1 (PKN) (58, 59). The sequences represented by XP\_009176240 (scaffold207685.g20343.t1) show the presence of the unique KA1 domain whose function is not yet determined. XP\_009174022 contains the glycogen recognition site of AMP-activated protein kinase. The AMPK1\_CBM is a closely related protein family associated with AMPKβ1 PF04739. The surface of AMPK1\_CBM carries a carbohydrate-binding pocket (60). XP\_009174737 contains FGGY domain that adopts a ribonuclease H-like fold and is structurally related to the C-terminal domains of carbohydrate kinase enzymes (61). XP\_009169681 contains the unique domain SMG1, which is a family of eukaryotic proteins that acts as an mRNA-surveillance protein in humans (62). In *C. elegans*, -SMG1 is a phosphatidylinositol kinase-related PK, known as a key regulator of growth. XP\_009168180 contains a unique domain called ATP-Gua Trans C and N terminal. The ATP:guanido phosphotransferase family consists of structurally and functionally related enzymes (63, 64) that reversibly catalyse the transfer of phosphate between ATP and various phosphogens. Protein XP\_009176739 contains a unique domain Mob1/phoceanin family. Mob1 is an essential *S. cerevisiae* protein that binds Mps1p, a protein kinase required for spindle pole body duplication and mitotic checkpoint regulation (65). Protein XP\_009164726 (scaffold16705.g1971.t1) contains the alpha kinase domain of ePKs catalytic domain. Protein XP\_009164726 (scaffold16705.g1971.t1) contains the alpha kinase family domain that are different from

conventional kinases but shows an unexpected similarity with ePKs in the catalytic core (66, 67).

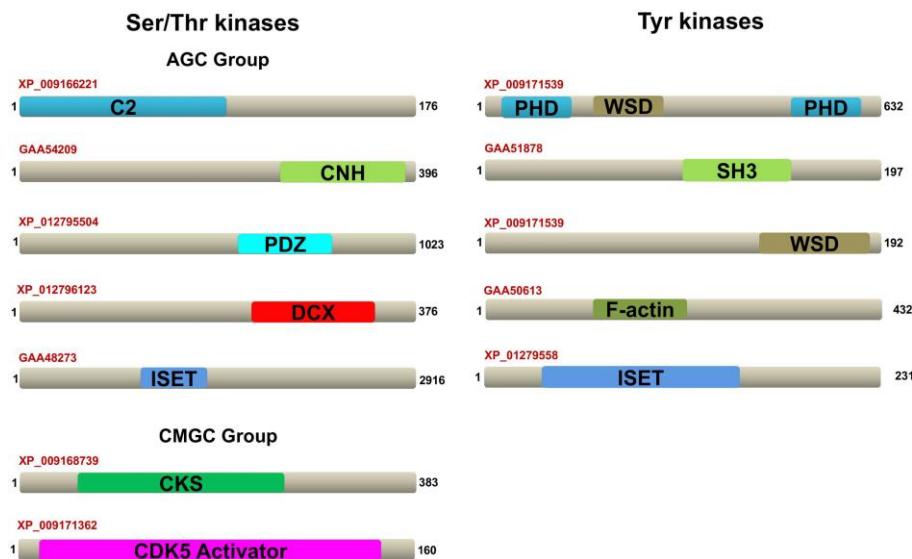

GAA28095 contains a novel domain PI3 kinase family. Certain members of the PI3K family possess Ras-binding domains in their N-terminal. These regions show some similarity to Ras-binding PF00788 domains (68). GAA53903 contains the γ-tubulin complex component, an N-terminal domain found in the components of the γ-tubulin complex proteins. The family members include spindle pole body components, such as Spc97 and Spc98, which function as the microtubule-organizing centre in yeast (69).

The kinases from Ser/Thr and Tyr kinase group with unique domains are shown in Figure 7, while the kinases from other group with their unique domains are shown in Figure 8.

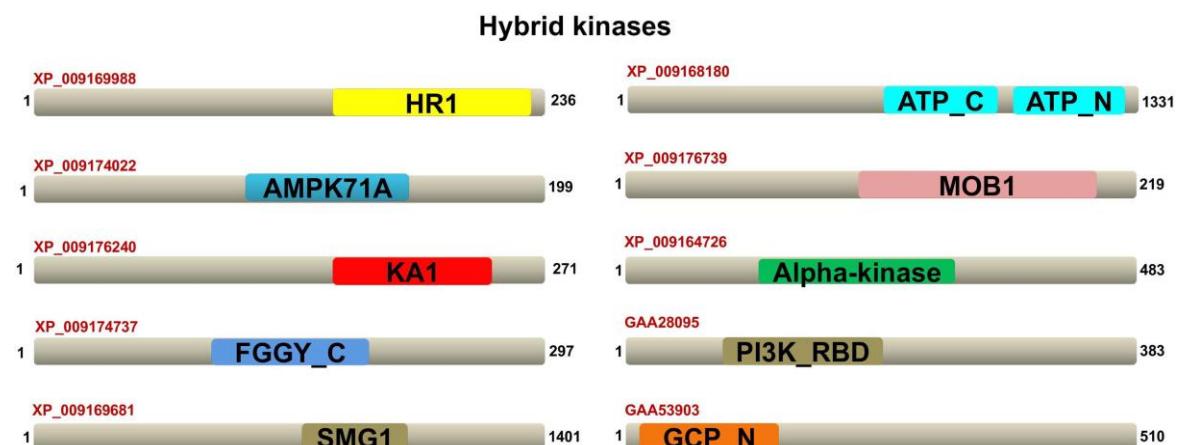

## 5. DISCUSSION

More than 90% of all the cellular proteins undergo phosphorylation at some point or other, which is primarily dependent on the balance between protein kinases and phosphatases. Any perturbation in this equilibrium may result in important cellular processes in an organism. In the present study we identified and classified 455 ePKs encoded in *F. gigantica* genome, which represents ~2% of the genes encoded in its genome, indicating the importance of protein phosphorylation for regulating the signal transduction processes of the parasite. *F. gigantica* represented kinases from each major ePKs group. Certain FgePKs have unique domains, which suggests the diverse nature of the proteins that can be exploited for designing novel inhibitors. For this, the FgePKs anticipated to have essential function in parasite survival can be selected followed by heterologous recombinant expression, purification and characterization of the ePKs. Nowadays, libraries based on the inhibitory scaffold structure of PKs are also available. Inhibitor library screening will allow identification and optimization of the predicted hits. Co-crystallization of the hits with the target ePKs can provide detailed view of the several interactions between the hit and the target ePKs (70). Reverse

## F. gigantica eukaryotic protein kinases

**Figure 7.** *F. gigantica* Ser/Thr and Tyr ePKs domain architectures. Representative domain organizations of some *F. gigantica* ePKs possessing unique domains are shown. The accession ID of the proteins are shown and their unique domains are highlighted in different colours.

**Figure 8.** *F. gigantica* 'others' ePKs domain architectures. Representative domain organizations of some *F. gigantica* ePKs possessing unique domains are shown. The accession ID of the proteins are shown and their unique domains are highlighted in different colours.

genetics approach has been utilised to characterise various parasitic kinomes (70, 71). Moreover, from this analysis of the *F. gigantica* genome, 115 kinases were derived that showed <35% query coverage when compared to human ePKs (Table 5). This phylogenetic distance between ePKs of *F. gigantica* parasite and their human host highlights significant divergences in their respective kinomes, further providing a platform for novel structure-based drug designing. Also, this information can be used to identify many

of the associated proteins that regulate ePKs activity. ePKs has been validated as potential targets for drug design and development as they play an essential role in several parasites. Furthermore, latest successful drugs bind ePKs near to the ATP binding site and block ATP access to the kinase to compromise enzyme activity (24). Thus, ePKs of *F. gigantica* with high sequence similarity to host proteins can also be used as targets since the inhibitor binds in non-conserved residues outside the ATP binding site. Also, the

unusual domains found in FgePKs can be used for designing more specific *F. gigantica* inhibitors. Since ePKs currently represents one of the most attractive drug targets, we are performing studies on the biochemical and structural analysis of FgePKs that we will address in further studies.

The present study provides a useful resource for the selection of high-priority

candidates for functional genomic and biological studies in *F. gigantica*. Methods, such as RNA interference, can now be used for the functional validation of ePKs-encoding genes in *F. gigantica*. In addition, immunological methods can be used for the identification of ePKs ligands and their localization in flukes. Using these tools, future insights into the roles of ePKs in these parasites could provide a path to understanding the

## **F. gigantica eukaryotic protein kinases**

molecular biology, biochemistry and parasite-host interactions of these flukes, and might help in the design of novel interventions. Evidently, this study provides information on ePKs for *F. gigantica* that will assist future investigations on both fundamental and applied levels. Improved annotation of ePKs from other flukes might also trigger broader comparative investigations.

## **6. ACKNOWLEDGMENTS**

Mr. Kanhu Charan Das and Dr. Parismita Kalita contributed equally to this paper. The authors declare that there are no competing interests. KCD and PK carried out the experiments. KCD, PK and TT analysed the data, conceived the study, participated in its design and drafted the manuscript. All authors read and approved the final manuscript.
